ARMY ENERGY FLOW

1.0 INTRODUCTION

The purpose of this study was to quantify energy consumption in the Army by fuel and by utilization. In performing the study several assumptions were made. This results from the need to supplement the existing meager data base. A discussion of each assumption, the methodology employed, and areas where improvements can be made are discussed below.

2.0 ASSUMPTIONS

- 2.1. Assumption 1. Average consumption per square foot for each category taken from Botros (Ref 1) is assumed to be a constant throughout the Continental United States or an average value. Since these numbers were obtained from three installations in and around the greater Washington, DC area they lack the randomness with respect to entire US and thus cannot be said to represent a true average consumption for America. A larger sampling population would add credence to the average consumption figure for the US. However, the consumption figures used are considered a "best guess".
- 2.2. Assumption 2. Total building area by category was obtained from the Building Information Schedule (BIS). It was assumed that energy was consumed throughout the area. However, error is inherent in this assumption since buildings in each category have spaces not receiving utilities. This problem is most severe in the storage category.

- 2.3. Assumption 3. Using boiler data from the Facilities

 Engineering Handbook "76" as a guide it was assumed that process loads

 account for 12% of the Army energy consumption.
- 2.4. Assumption 4. The following conversion efficiencies have been assumed:

FUEL and continues does to no	tea base % discussi	
Anthracite Coal	energy 269 .65 ye .bey	mechadology employ
Bituminous Coal	.65	
Electricity	.95	Z.O ASSUMPTIONS
Fuel Oil 1007 shaups red notique	chen 1. 7. erage cons	
Natural Gas	Mary sorts men os	
Purchased Steam & Hot Water	et mente 8, belief	
Propane	med from three that	

Since no standard efficiencies exist for Army facilities these efficiencies were chosen a priori and are considered realistic.

3.0 METHOD OF ANALYSIS

- 1. Consumption data by fuel was gathered from the DEIS reports.
- 2. Reports on total area by category were requested from Real Property.

 Table I shows the breakout by category number.
- 3. Using the assumed efficiencies utilized energy and the wasted energy were calculated.
- 4. Using consumption averages from Botros' study the number of BTU's consumed by category was obtained.

- 5. Summing the results of step four, the total consumption was obtained. With this number as a base the percent consumption was calculated for each category.
- These percentages were then multipled by total energy
 consumption obtained in Step 1 (DEIS) to yield energy consumption by each category.
 4.0 RESULTS
 - 1. Table II, Figure 1, Energy Flow Chart by Fuel.
 - 2. Inventory of Army Buildings by Category.
 - a. Army Total, Table III.
 - b. By major commands, Table IV VII.
- 3. Army energy consumption by category and major command, Table VIII, Figure 2.
- Input energy to Army boilers & heating plants, Figure 3.
 ALTERNATIVE APPROACH

The major problems of this analysis were discussed with each assumption. These problems are briefly outlined below:

- 1. Assumption #1
- a. Limited data base for calculating Army US consumption per unit area by category.
 - b. Data non-random
 - 2. Assumption #2

Areas not receiving utilities are included in category totals.

3. Assumption #3

Assumed process load of 12% and conversion efficiencies lack a firm quantitative base.

A random sample by similar climatic region of each category could be obtained since all the required information is cataloged on a computer file. The sample population size can be determined by assuming a normal distribution of facilities as a function of consumption per square foot.

This assumption is justified under the central limit theorem.

Assumption two can be improved by querying the utility service column of the BIS and excluding buildings not having utility services. This will eliminate buildings not consuming energy, however, the BIS does not distinguish between gross area and that which is served by utilities. Thus areas not receiving utilities cannot be totally excluded when using the BIS.

Assumption 3 & 4 will require extensive metering since no field data exists at the present time.

Due to the above considerations the results are of questionable validity for anything other than gross calculation or rough estimates.

BREAKOUT OF BUILDINGS BY CATEGORY NUMBER

Building Type	Category Number
Training	170
Maintenance	200's
